INF	Computer science
MAP	Applied mathematics
MAT	Mathematics
PHY	Physics
MEC	Mechanics
BIO	Biology
LAN	Language
HSS	Humanities and Social Sciences
ECO	Economics
MIE	Management and Innovation of Entrepreneurship

#### First year (Core curriculum):

INF371	This course presents the advanced features of programming languages, and in particular
Mechanisms of	the object-oriented constructs of Java. These features are extensively presented and then
object-oriented	used in programming classes. The way they function is detailed by showing how they are
programming	translated, or compiled, to an abstract machine. This last point allows also an opening
	towards computer architecture.
Professor:	This course is for first year engineering students who already know some programming and
Benjamin	basic algorithmics.
Werner	The course is graded through a two hours final exam, with some modulation by the work
	done in the programming classes.
MAP361	This course introduces the basic concepts of probability theory, i.e. the mathematical
Random	analysis of phenomena in which chance is involved. Particular emphasis will be placed on
	the two major concepts that underpin this theory: conditioning and the law of large
Professor:	numbers. The aim of the course is to develop probabilistic reasoning, probabilistic modeling
Josselin	and simulation. This modeling is fundamental in many fields of application. The course is
Garnier	illustrated by examples and numerical experiments. It also introduces a few notions of
	measurement theory (which is the axiomatic foundation of probability theory) and provides
	an introduction to statistics. During the course, students will complete a simulation project
	in pairs, which will count towards the module grade.
MAT361	MAT361 is one of the two core courses offered by the Mathematics Department at École
Introduction to	Polytechnique. It is designed for students from streams where mathematics has been given
real analysis	less emphasis.

	This is an analysis course, divided into four successive parts:
Professor: Yvan	1. Topology of normed vector spaces
Martel	2. Differential equations
	3. Integration complements
	4. Hilbert spaces and applications.
PHY361	Quantum mechanics is probably one of mankind's most fertile intellectual adventures of
Quantum	humankind. It has made it possible to determine the structure of nuclei, atoms and
mechanics	molecules, elucidate the nature of light, and is an indispensable tool for understanding
	modern physics, from elementary particles to the stars and the Big Bang. Its economic
Professor:	impact is just as important: most of the world's high-tech products (electronics, lasers and
Manuel Joffre	optronics, nanotechnologies telecommunications) are directly derived from quantum
	concepts.
	The aim of PHY361 is to provide all students with an introduction to introduction to
	quantum mechanics and some of its applications. It begins with wave mechanics. After the
	basics of the theory, we'll study a few one-dimensional problems one-dimensional
	problems, such as the motion of a particle in a square-well and the harmonic oscillator. This
	will introduce the notion of quantum states and introduce the general principles of
	quantum mechanics, using the using Dirac's formalism. The operation of masers and
	quantum cryptography will serve to illustrate these principles. This course will have close
	links with both mathematics and probability.
HSS/BIO361	1. Introduction to questions and methods of cognitive sciences: the example of decision-
Cognitive	taking
sciences	2. The baby statistician: cerebral development and early intuitions
<b>.</b>	3. Cerebral mechanisms for acquiring reading skills
Professor:	4. Cerebral mechanisms for mathematical operations
Stanislas	5. Modern analysis of the conscience question
Denaene	6. The big principles of learning
ECO361	This course presents the basic principles of economic sciences.
Introduction to	
economics	
Drofossori	
Professor:	
Olivier Gossner	

### Second year:

INF421	Algorithms are the heart of all computation. This course, building on the algorithmic
Design and	foundations laid in the first computer science courses (INF321 or INF311+INF411), equips
analysis of	the student with a solid background in modern algorithmics. Having followed this course,
algorithms	the student will have a profound knowledge of the most central algorithms, both
	understanding how and why they work and being able to solve a wide range of
Professor:	computational problems with these building blocks. This is material that everyone aiming to
Benjamin	work in a computer science or computing related context needs to know, let it be in a
Doerr	research or industrial environment. In addition to this, we shall also give a brief
	introduction to several more recent topics like randomized algorithms, evolutionary
	algorithms, online algorithms, or algorithmic game theory, which had a significant impact
	on how we understand computing today. The course is taught in English (amphis, poly), for
	all the rest including the exam both French and English are offered.
INF442	Modern data analysis relies on high-level languages such as Python or R for data
Algorithms for	manipulation and processing. However, behind standard libraries like Scikit-Learn lie
data science in	implementations in low-level languages like C or C++ for optimized execution and efficient
C++	management of memory or computing resources. Hence the interest of this course, which
	has a dual objective: on the one hand, to familiarize students with some of the standard
Professors:	data analysis and machine learning techniques; on the other, to acquire C/C++
Guillaume	programming skills that will enable students to adapt existing low-level implementations to
Février / Pierre	their specific needs. It should be noted that the programming paradigms covered in the

Aguié	course are almost exclusively sequential, with concurrent programming barely touched on
	in the last session and reserved for other courses.
INF443	In addition to its importance for digital entertainment (video games, special effects, 3D
3D Computer	animated films), 3D computer graphics is indispensable for industrial virtual prototyping
graphics	(design of objects or mechanisms intended for manufacture), learning simulators and other
Duefersou	"serious games", as well as scientific visualization, for example for visual exploration of data
Protessor:	or simulation results.
Damien	This course covers an aspects of computer graphics, focusing on the interactive side. In
Konmer	3D animation.
INF472R	Robots are complex systems comprising a variety of sensors, actuators and algorithms that
Robots and	link them together to interpret the environment, model it, plan movements or manipulate
drones	it. Developing software for these systems is therefore difficult, and approaches that
	abstract from specific hardware or reuse existing components are being developed to
Professor:	simplify the task. Algorithms and their proof of correct operation, in the presence of the
David Filliat	many uncertainties due to sensors and actuators, are also a major issue in UAV
	development.
	In this modal, we'll look at some programming basics (python, C++), the basic principles of a
	middleware used in many laboratories and industries (Robot Operating System, ROS), some
	notions of image processing, 3D point cloud processing, control, mapping, planning and
	navigation for robotics, as well as associated open-source libraries (OpenCV, PCL) and
	guaranteed simulation methods to ensure the correct operation of the chosen algorithms.
	various robotic platforms (quad-rotor drones, wheeled mobile robots, humanoid robots)
	and sensors (RGB cameras, depth cameras, laser rangefinders) will be made available to
MAD/22	This course has three objectives. The first is to introduce the tools of mathematical
Statistics	statistics and machine learning. We will describe everything from the choice of a statistical
Statistics	model to parameter estimation inference and model selection. We'll learn how to build
Professor: Eric	estimators, tests and classification rules, and how to evaluate the performance of these
Moulines	rules. We will introduce a number of theoretical tools - decision theory, empirical
	processes. The last two courses will be devoted to an introduction to statistical learning.
	The second objective is to describe, in the course and in small classes, concrete examples of
	modelling in various fields (signal and image processing, econometrics, environmental
	sciences, shape classification, etc.). The third objective is to develop a well-founded
	practical know-how enabling students to understand how theoretical tools can be
	implemented in concrete applications (use of R or Python).
MAP435	This course is an introduction to optimization and control of dynamical systems which are
Optimization	instrumental in the design and management of systems arising in science, technology,
and Control	industry or services.
Drofossor	The first part of the course is devoted to optimization, including or not constraints, in finite
Professor:	or immite dimensions. After introducing some theoretical results on optimality conditions,
Gregolie Allaire	on some important classes of problems, like linear programming or sequential quadratic
	nrogramming
	The second part of the course is concerned with the control of differential equations.
	modelling time evolution problems. The notions of controllability, adjoint state and the
	minimum principle of Pontryaguine are the key ingredients introduced here.
	Beyond these technical tools, this course is also intended to illustrate the typical approach
	of applied mathematics which mixes modelization, mathematical analysis and numerical
	simulation, all these aspects being crucial in any innovative processes.
MEC430	This course introduces the fundamental concepts of deformable continuum mechanics
Deformable	within the simplified framework of slender structures. The aim is to introduce all the
continuum	concepts within this restricted geometrical framework, so as to quickly arrive at
mechanics	applications and deal with numerous phenomena with a simplified mathematical
Drofosson	Tormalism.
Basile Audoly /	the approach used is similar to that of other more specialized courses, and in particular to that of MECA21 for the case of three-dimensional structures; we will cover the patients of
Dasile Audoly /	that of MEC451 for the case of three-unnensional structures. We will cover the hotions of

Marige         behavior laws and boundary problems.           Once this framework has been introduced, we'll focus on solving the problems obtained and large displacements.         Static problems involving elastic wires, rods, beams or arches will be studied, enabling us to deal not only with the classic problems of strength of materials, but also with more advanced problems such as buckling instabilities or boundary layers.           Finally, we will introduce the variational approach, which on the one hand offer a different view of the physical laws governing structural mechanics, and on the other provides mathematical and numerical tools for solving the equations. In particular, this will enable us to obtain fundamental energy properties, define stability concepts and provide an introducting the their provide and thermodynamics: what distinguishes a fluid from a solid? We'll then look at how the complexity of these problems can be further reduced, sometimes to the point of no mathematical resolution at all, thanks to dimensional analysis and the principles of similarity on which fluid mechanics experimentation is based. We will then take a closer look at the perfect-fluid approximation that underpins many of the historical applications of fluid mechanics. Analysis of perfect-fluid flows highlights the special role of vorticity, and we'll explore "vorticity dynamics", which can be considered a discipline in its own right. We will then show how the perfect-fluid approximation can be connected to another approximation, in order to obtain a uniformly valid description of any flow. Finally, we conclude this course with an introduction to turbulence, which today represents one of the main frontiers in our understanding of fluid mechanics.         PHY431       The objectives of this course are diverse. Firstly, this course provides the necessary prerequisites for all those who wish to continue with fundamental physics ("from particles to stars") in their third year and beyond. Secondly, for students interested in aspects of the concepts we will be covering in this course.         Professors:       David Langlois       This course provides a broad introduction to an essential field and prepares for several other 2nd year biology courses, as well as for more advanced, 3rd year programs. This course provides a broad introduction to an essential field and prepares for several other 2nd year biology courses, as well as for more advanced, 3rd	meenames	fluids? What is a Newtonian fluid? We then go on to explain the fundamental principles of
Laurent Jacquin       fundamental equations of Newtonian fluid mechanics: the Navier-Stokes equations. These equations, although reputed to be among the most difficult in physics, are analyzed and calculated by engineers and researchers on a daily basis. We'll then look at how the complexity of these problems can be further reduced, sometimes to the point of no mathematical resolution at all, thanks to dimensional analysis and the principles of similarity on which fluid mechanics experimentation is based. LAN483kANG	In this class we will read stories by Isaac Asimov, Arthur C. Clark, H.P. Lovecraft, and
Science Fiction	excerpts from novels by Philip K. Dick, Ursula K. Le Guin, H.G. Wells, and others. We will
	also examine films such as 2001: A Space Odyssey, Blade Runner, Alien, Children of Men,
Professor:	Arrival and Ex Machina. This body of literature and cinema will be placed in its social and
Christopher	historical context, as we trace the links between science fiction and the western literary
Robinson	and artistic tradition from antiquity to the 20th century. We will also address a number of
	current social, philosophical and linguistic issues, especially posthumanism and the defining
	principle of the genre: cognitive estrangement. Finally, we will look at the three major
	techniques that authors employ in the construction of an imaginary space and time:
	analogy, extrapolation, and world reduction.
LAN412RUS	Russian, an Indo-European language, has many similarities with the languages generally
Russian for	studied in France. However, it is an extremely original language for a Westerner. The way of
beginners	thinking is not the same, and it responds to values that are totally unusual for this same
	Westerner.
Professor:	The Russian for Beginners course is based on principles and a method that are valid for all
Tatyana	three semesters at the Ecole. The Polytechnicien leaves the school having seen the whole
Shukan	of the grammar, "chatting" fluently, and with all the means to continue studying the
	language on his own if he so wishes.
HSS422	The aim of this course is to provide the means for thinking about the quantification of
The power of	economic and social facts. It proposes theoretical concepts, inspired by the work of Alain
numbers in the	Desrosières, to analyze quantification. Several quantitative objects will be examined, with
economic and	the aim of revealing their socio-historical construction process.
social world.	
Socio-history of	
quantification	
Professor:	
Arthur Jatteau	This source will draw on the recourses of philosophy (as well as the seriel asian ser) to well
Can one still be	to the test the diagnosis that our age no longer has the means (nolitical sciences) to put
modern?	collogical) to be modern. To do this, we'll start by asking what evactly modernity means a
modern	term that is more often invoked than defined. We'll then look at some questions whose
Professor:	resolution seems urgent today: are the achievements of reason always reasonable? Having
Michael	believed in progress, are we condemned to wait for catastrophe? If we can no longer bank
Foessel	on the future, should we rediscover a sense of tradition? Is the individualistic freedom of
	the modern age the cause of identity problems and a new solitude? Is the taste for novelty
	nothing more than an incantation to be "disruptive"?
HSS415F	Does science have a history? Often celebrated for their universality, the sciences can seem
History of	timeless. Yet scientific and technological knowledge is developed by men and women; it
science and	evolves in social times and spaces, interacting with other cultural, social, economic and
technology	other activities. The aim of the seminar is to develop a reflective approach to science, while
	providing an introduction to research in the history of science. The presentation of major
Professor:	contemporary research themes will enable participants to discover the richness of highly
Frederic	interdisciplinary approaches, including history, philosophy and sociology.
Brechenmacher	
HSS413G	This seminar is meant to be a trip from drawing on paper to modern digital animation tools.
The	We will focus on how to make an information accessible, wether it is for students,
sketchbook,	scientifics, general public, or even children.
from drawing	A series of workshop will allow us to address different thematics:
to movement	- rundamental aspects of drawing (the "stroke")
Professor	- composition or drawings (on paper, and with a software)
Professor:	- animation approaches in the so-called 2D Tariniy (Irame by Irame, stop-motion,
Chabrier	waiping) - compositing softwares and short film-making
Chaptier	Students will have to develop a parration through text and images in order to produce the
	state is a set of the

	Warning: vector animation and 3D animation will not be adressed in this course. However,
	student who are already skilled in such domains are welcome to use them in their movie.
MIE431	Organizations (companies, research laboratories, public services, etc.) are omnipresent in
Fundamentals	our daily and professional lives. They shape our lifestyles and our societies. Powerful tools
of	for organizing and sustaining collective action, they will be the focus of your professional
organizations	life, whatever career you choose.
	Although seemingly familiar, they are nevertheless complex in their dynamics and in the
Professor:	multiple dimensions, both technical and human, that make them up. For more than a
Véronique	century, management science - the science of the "company", in the sense of the
Steyer	undertaking and the result of this dynamic - has sought to better understand how they
	work, and to provide managers with benchmarks and tools to steer their internal and
	external complexities.
	The aim of this course is to give you a few keys to understanding the logic of this new
	territory, and to increase your ability to act within it, both during your internship at the end
	of this second year, and later in your professional life.

## Third year:

MEC552A	Numerical simulation has long become an indispensable tool in all areas of mechanical
Numerical	engineering. In research, numerical simulation allows us to obtain information of
methods for	mechanical systems in a level of detail that is usually inaccessible from experiments. In
fluid mechanics	applications, it is used for parameter studies, optimisation and virtual prototyping. This
	course provides a thorough introduction to numerical techniques for the solution of linear
Professor:	systems, ordinary and partial differential equations, as needed for computational fluid
Lutz Lesshafft	dynamics. The fundamental issues of consistency, stability and convergence of numerical
	methods are treated, while maintaining a focus on their practical application.
	The course is taught in English, integrating lectures with practical exercises. Numerical
	methods will be implemented in Python, using the Jupyter notebook format.
MEC554	Shock wave? You probably already heard this term but what it means? What are the laws of
Compressible	physicsgoverning such a wave and its properties? In which basic fields of fluid mechanics
aerodynamics	such wares areencountered and play a key role? What are a so-called compressible flow
	and the usual fundamental properties of such flows? This course brings answers to the
Professor:	above issues. Upon adopting a few simple assumptions (which are quite relevant for most
Antoine Sellier /	of the applications in this field), it derives the main properties of compressible flows. More
Benjamin	precisely, it successively dealswith shock waves (birth and properties, either plane or
Leclaire	curved ones), shock-boundary interactions, one-dimensional unsteady and two-
	dimensional steady compressible flows, steady compressible flows about a thin airfoil (with
	subsonic, supersonic and transonic regimes), On the theoretical side, the course also
	examines the nature (elliptic, hyperbolic,parabolic) of the Euler equations (unsteady one-
	dimensional or steady two-dimensional ones) and also introduces in a more general frame
	work the useful method of characteristics. Such a method is illustrated in this course for
	some encountered compressible flows.
MEC560	Study of the different types of animal propulsion and comparison with human systems. The
Propulsion	first part of the course is dedicated to the swimming (low and high Reynolds numbers). The
	second part is about flight (gliding flapping, steady). The last part of the course covers
Professor:	human propulsion (planes, helicopters, boats),
Christophe	
Clanet	
PHY550	This course deals with the physics of ionized environments, or plasma physics, from the
Plasmas in	space science and industry point of view. Plasma is by far the most common state of matter
space science	in the visible universe and therefore nearly all astrophysical objects are in fact plasmas.
and technology	Plasmas are also present on Earth, either created by nature in the form of lightnings or
	auroras or generated by human beings in a wide range of industrial applications. They play
Professor:	a central role in microelectronics since etching and deposition of thin films relies mostly on
Pascal Chabert	plasma processing. They are also used as air purifiers or to treat wounds in medicine. They

	might be used in the coming years to treat cancer or to achieve nuclear fusion, which would
	give humanity an almost unlimited source of energy. As we shall see in details in this
	lecture, they are now successfully used as efficient engines for satellite and spacecraft
	propulsion. Thus, plasmas are fundamental in space science and technology. Satellites and
	spacecrafts mainly operate around Earth, or in the solar system in environments that are
	almost always significantly or fully ionized. The Sun continuously emits a magnetized
	plasma, mainly composed of electrons and protons, called the solar wind. This plasma
	interacts with the planets of the solar system, leading to complex phenomenon that are
	essential to understand the life and the dynamics of planets and their atmospheres. Planets
	that generate their own magnetic field, like Earth, are partially protected from the solar
	wind by a magnetosphere, which acts as a magnetic shield. Nevertheless, the higher
	atmosphere remains ionized by the solar wind (the ionosphere), particularly in the aurora
	regions. This course will therefore require a detailed description of the fundamental
	principles governing the solar environment, the solar wind, the magnetosphere and the
	Earth ionosphere. The lecture will then describe in details the interaction between plasmas
	and satellites or spacecrafts. These are immersed in space plasmas and are subject to
	charged particles bombardment (electrons and ions). We will study the structure of the
	potential surrounding a satellite in a plasma and the variety of interactions between
	charged particles and parts of a satellite. The conductivity of its dielectric coating, also
	subjected to radiation, determines the charge differential or charge risk. The secondary
	emission of electrons resulting of the impact of the plasma electrons controls the sign of
	the electrostatic discharge, impacts the multipactor discharges which limit the power of
	telecom satellites, and modify the abnormal electronic conductivity in Hall effect thrusters.
	In the last part of this course, we will describe the fundamental mechanisms at play in
	plasmas thrusters, that are now routinely used as satellite engines, and that will be
	essential for future space exploration missions. The principle of plasma thrusters is to ionize
	the gas propellant to achieve much higher exhaust velocities than conventional
	hydrodynamic nozzles. For the same thrust, the mass flow of the propellant is then
	drastically reduced, and the plasma thruster has a much better mass efficiency than
	conventional chemical engines. We will study in details two flight-proven engines, the
	gridded-ion thruster and the Hall effect thruster. Different types of plasma thrusters based
	on advanced concepts currently under development will also be discussed.
PHY569B	The solar system provide an ideal laboratory to investigate fundamental physical processes
Astrophysical	(e.g., turbulence, magnetic reconnection, shocks) that underlie longstanding problems of
plasmas and	heliophysics, such as the solar corona and solar wind heating problems, particle
space missions	acceleration and radio emissions in planetary magnetospheres (e.g., aurora). The main
-	reason is the availability of high quality in-situ data measured by various spacecraft that
Professor:	have been exploring these media for about a half century. These include the solar wind
Fouad Sahraoui	exploration by Voyager since the 1970s to the more recent ones, the NASA/Parker Solar
	Probe (launched in 2018) and the ESA/Solar Orbiter (launched in 2020), the near-Earth
	space exploration (ionosphere and magnetosphere) by multi-satellites missions such as the
	ESA/Cluster (2000) and NASA/MINIS (2015), planetary exploration: NASA/Jupiter by Galileo,
	Juno (2010) and Soon ESA/JUICE (launched in 2022, orbit insertion in 2030), NASA-
	ESA/ Saturn (Cassini 1997-2017), Mercury by NASA/Messenger (2004) and ESA-
	achievements accomplished in the color system allow us to extrapolate the results to other
	challenging problems of distant astrophysical objects, which are not (or much less)
	accessible to measurements. Examples are star formation in the interstellar medium (ISM)
	cosmic rays acceleration and magnetic field generation in galaxies and inter-cluster galaxy
	(ICG), angular momentum transport and accretion flows around compact objects (e.g.
	black holes). In this lecture we will first introduce some major questions of astrophysical
	plasmas and explain how they can be tackled using the solar system as a laboratory to test
	modern existing theories. In the second part, we will recall some basic equations of plasma
	physics (kinetic and fluid-like descriptions, i.e. MHD and its extensions to small scales, e.g.
	Hall-MHD), before discussing examples of universal plasma processes such as turbulence
	and magnetic reconnection. We will expose the underlying theories of such processes and
	explain how they can help solving some of the questions addressed in the introduction of

	the course, with a particular focus on how the theoretical predictions can be tested in spacecraft observations. The second part of the lecture we will deal with the description and design of space missions dedicated to space plasmas. We will describe the main in-situ instruments embedded on orbiting spacecraft (e.g., AC & DC magnetometers, Langmuir probes, plasma spectrometers –electrons and ions). We will explain their functioning principle, their constraints and limitations inherent to space exploration (cost, mass, power,
	telemetry). We will also introduce some signal processing techniques and methods used to analyze (single and multi-)spacecraft data and discuss their strengths and weaknesses. In the last part we will present some current trends in space exploration dedicated to plasma physics (both in the solar wind and planetary magnetospheres). We will introduce new
	scientific questions that emerged in light of recent progress achieved from the current orbiting spacecraft, discuss the new concepts of space missions under preparation and highlight the new technical challenges faced.
PHY569C Orbital	The recent advent of nanosatellites, the announcement of new mega-constellations of satellites including thousands of units, along with the contemporary awareness of the risk
dynamics and multidisciplinary	posed by space debris, have all in common the need to understand the behavior of bodies in orbit around Earth, in the short and long-term range. This issue falls under a field called
optimization	astrodynamics, or more generally orbital dynamics. This domain being a branch of celestial
Professor:	mechanics possesses therefore a long history, and proceeds from dynamical systems theory and analytical mechanics in its mathematical and physical foundations. It is still an active
Fabien Gachet /	field of research, with for instance the recent use of tools stemming from chaos theory to
Mathieu Balesdent / Loïc	study the long-term stability of orbits: we can mention the computations of chaos indicators in order to determine the best solutions for satellites' end of life (reentry or
Brevault	graveyard orbits), or also the study of orbital resonances present in some regions of space
	so that satellites naturally end up reentering. In this part of the class we will study the Hamiltonian formulation of orbital dynamics, the resolution of its equations, either
	analytically using series expansions, or numerically using specific numerical integration
	schemes, we will develop the perturbation approach and we will analyze the different
	detection tools previously mentioned, and we will examine a cartography of the dynamics
	in the different orbital regimes used for Earth orbiting satellites, as well as the management
	of the space debris problem and the risks of collisions. Aerospace vehicle design is a complex process involving numerous disciplines such as
	aerodynamics, structure, propulsion and trajectory. These disciplines are tightly coupled
	and may involve antagonistic objectives that require the use of specific methodologies in order to assess trade-offs between the disciplines and to obtain the global optimal
	configuration. Generally, there are two ways to handle the system design. On the one hand,
	Optimization): the designer of each discipline has to design its subsystem (e.g. engine) taking the interactions between its discipline and the others (interdisciplinary couplings)
	into account. On the other hand, the design may also be considered as a whole: the design team addresses the global architecture of the space vehicle, taking all the disciplinary
	design variables and constraints into account at the same time. This methodology is known
	as Multidisciplinary Design Optimization (MDO). The course draws a panorama of the specific mathematical tools used to handle space vehicle design problem complexity:
	formulations of the MDO problem, choice of the adapted optimization algorithms, use of
	machine learning techniques to reduce the computational costs and the integration of high- fidelity simulations, etc.
HSS522	For two decades, the number of digital available skyrocketed. Collected by sensors installed
Big Data	in our daily life, this information is a digital record of individual and society. This evolution,
sociology	combined to the use of technologies to treat them (first and foremost AI), has caused intense debates.
Professor:	How do they change our lives? From social science work that invested various fields going
Etienne Olion	through these big data, the aim of this course is to provide precise answers to the questions
	that have been raised in the public depate. Rather than giving a too general overview, we will cover specific topics. Among those: work (are we witnessing a labor market
	urbanisation?), privacy (are we witnessing a feeling, meeting commodification), science (do

	we really know more today?) and techniques (what can AI do?), political organization and public debate (is democracy possible with mass surveillance and social media?). From these examples, this course will study the transformations involved in this new disponibility of
	data, and the structures that collect, transport and store them.
HSS512F	Consciousness is still a new notion in cognitive science. It was considered to be a notion too
Brain and	vague or subjective to be rigorously and empirically studied with psychological,
cognition: The	neuroscience and modeling methods. The situation changed in the last 25 years with the
consciousness	implementation of experimental protocols allowing the systematical comparison of
	supraliminal (where a stimulus gives rise to a perception associated with consciousness)
Professor:	and subliminal (where a stimulus is dealt without the subjects reporting having perceived
Jérôme Sackur	anything) perceptions. These protocols enabled implementing cognitive and neuronal
	models that given legitimacy to empirical sudy of consciousness.
	In this seminar, we will start with the study of model of perceptive consciousness that are
	now classic, which without being completely consensual form a solid base for discussion. I
	will present basic methods and concepts of the empirical study of consciousness,
	experimental psychology, neuroscience and modeling. Then, we will look at the boundaries
	of the field, because of course our consciousness of our perceptions is only one aspect of
NAIEE 24	The question.
IVIIE524	for these new platforms illustrates the success of these initiatives and to think that
